TME 005 | MICROBIAL AIR MONITORING SYSTEM

The equipment uses isokinetic sampling, which delivers uniform airflow across the surface of an agar plate at high velocity for quick analysis. A specified volume of air is passed through small holes or slits onto a petri plate containing culture medium for a specified period of time. After the cycle is complete, the plate is removed from the air sampler and incubated, and visible colonies are counted to determine the level of contamination. This will result in the number of viable microorganisms present in each liter of air in the area being calculated.
